

Explicit Model Predictive Control for Nonlinear Systems

Projectseminar (2-4 students, homeoffice possible)

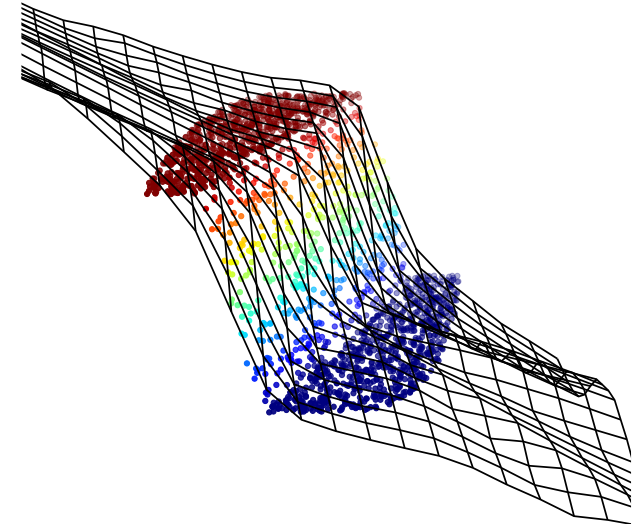

Model Predictive Control (MPC) is an advanced control method that can naturally handle nonlinear systems subject to constraints. However, for MPC, we need to repeatedly solve a complex nonlinear programming problem (NLP) online. Consequently, MPC is often out of reach for real-time application. Explicit MPC tries to surmount this problem using multiparametric programming techniques to characterize the optimal control law offline. Instead of solving the optimization problem during online operation, the control action can then be determined by evaluating an explicit function of the current state. The focus of this project is on implementing and illustrating approaches of explicit model predictive control. The final report must be written in English. Meetings during the project can be in English or German.

Requirements:

- Strong programming skills (Matlab or Python) are essential for this topic
- Knowledge in optimization and MPC
- English

Tasks:

- Literature review on explicit model predictive control
- Design of a nonlinear model predictive controller
- Implement approaches for explicit MPC of nonlinear systems
- Demonstrate the approaches on self-selected examples
- Approximation via (conventional) regression methods
- Evaluate, compare and present the results
